Abstract

This paper describes a step-by-step approach for moving the 1990 Census Transportation Planning Package data from its proprietary extraction format to a commonly used Geographic Information System platform. This paper was prompted by several needs. First, was the fact that the 1990 public release version of the data resides in a proprietary software written to run with Windows98 and NT 4.0 or earlier operating systems. It will not run on the newer versions of Windows 2000 or NT 5.0. Second and more important, were the many requests from the user community for some guidance on a conversion process. By providing the user community with the guidance described in this paper we hope to help extend the utility of the data for many years to come.

This paper is organized into three sections. Section 1 is a general introduction to the topic. Section 2 illustrates the general principles for doing a conversion, while section 3 presents a detailed step-by-step demonstration for the Washington D.C. area.

Disclaimer

This document was prepared to assist those who want to use the 1990 CTPP data in a GIS platform, specifically Arcview. We are aware that this may not be the only way to do the conversion, nor are we endorsing any software by demonstrating our method. This must be treated as a “working paper” developed for the sole purpose of helping the CTPP user community to effectively use the 1990 CTPP. Neither we, nor our employers, specifically the U.S. DOT endorse this as the only method, or endorse any of the software referenced in the paper. While we took care to test the method, we do not own any legal responsibility if this method does not work.

1.0 Introduction

When the 1990 Census Transportation Planning Package (CTPP) data became available, it was packaged in one of two ways. The first releases were distributed to States and MPOs in a format approximating the more traditional census products such as the STF (Standard Tape Files) and PL (Public Law) -94-171 series. These first releases came with no extraction software and required an experienced programmer and sophisticated software (such as SPSS, SAS etc.). While this worked for many of the advanced users, most preferred to wait for a CD-ROM version packaged with its own extraction software.

The CD-ROM version was developed under a Bureau of Transportation Statistics (BTS) contract and featured extraction software called TRANSVU. TRANSVU was developed as proprietary software by Caliper Corporation. This software allowed the users to “custom” view the data, map it and print selected tables. For the first time in the history of the CTPP development, TRANSVU filled the need for general-purpose extraction software. Although the database used TRANSVU for its extraction it was readily exportable to several GIS packages including TRANSCAD, or Maptitude. While this served several users very well, there were others who expressed the desire to move the data from TRANSVU to other GIS platforms and applications. This paper addresses that need.

TRANSVU was developed under a DOS-based operating system for Windows 3.1 or Windows 95. Later modifications were purchased which allowed it to run on Windows98 and Windows NT. However, as operating systems keep evolving the original sponsors of the CTPP data product have not been able to keep pace with continued purchases of new patches. As a result, we have arrived at a point in time when TRANSVU will not run on the latest Windows operating systems (Windows 2000 or NT 5.0).

Since TRANSVU did not allow the data to be easily exported to GIS formats other than TRANSCAD and that operating systems were restricting its use, the need to provide for the on going preservation of the data by the user community became paramount. This paper was written with that spirit in mind.

The remainder of this paper is divided into two parts. The first presents a general overview of how to move the basic data into a GIS format. The second, and more important takes the user though a step-by-step application using the ESRI Corporation product, ArcView. **It must be noted that although this paper uses an example for a specific software it in no way should be construed as a product endorsement.** This paper was prepared with the sole purpose of providing the CTPP user community with a framework/methodology for preserving the basic CTPP data.

Questions or suggestions on improving this paper are appreciated. Send you comments to Nanda Srinivasan at ns@camsys.com

2.0 General Instructions

2.1 Prepare Your Base GIS Layer from TIGER

The ESRI website has all the 1995 TIGER/Line files converted to shape files available for free. For more information, please visit

<http://www.esri.com/data/online/tiger/index.html>

ESRI also supplies enhanced version of TIGER/Line, and tips on using TIGER/Line along with other spatial databases.

Alternately, you can follow these steps:

Step 1: Download any version of TIGER/Line from 1994-1998 that contains a TAZ layer from the Census Bureau website.

Step 2: Buy any commercial software that can convert TIGER/Line to a GIS Format

Tip: GIS Tools contains a commercial software to convert TIGER/Line to GIS formats.

The website is www.gistools.com.

The vendor's description on the website states:

TGR2SHP and TGR2MIF Description:

TGR2SHP and TGR2MIF are 32 bit Windows applications for converting TIGER 99, 98, 97, 95, 94 and Census 2000 Dress Rehearsal files to ArcView shape files and MapInfo MIF/MID files, respectively. Version 4 of these programs have many features which make converting TIGER files a simple matter of point-and-click.

Another way to create a TAZ layer is by using equivalency files from the CTPP. The 1990 CTPP package also came with a block to TAZ equivalency file. These can be used to establish the geography files for the TAZ layer from blocks in TIGER/Line.

2.2. Obtain TRANSVU and 1990 CTPP CD-ROMs

Step 1: Obtain the 1990 CTPP and software from Bureau of Transportation Statistics for free.

To order for Statewide element, please visit:

<http://206.4.84.245/btsproducts/category.cfm?Category=111>

For the Urban element, please visit:

<http://206.4.84.245/btsproducts/category.cfm?Category=110>

Tip: You can also e-mail the CTPP Working Group at ctpp@fhwa.dot.gov to order.

Follow the instructions provided on the CD-ROM and install TRANSVU and the data base for the area desired. To run TRANSVU on NT 4.0, you will need a patch. It can be downloaded from: <http://www.bts.gov/programs/btsprod/setupnt.exe>. Should you have

any problems the data you can telephone the BTS Product Distribution Center at 202-366-DATA (202-366-3282).

Note: TRANSVU will not work on Windows 2000, or NT 5.0. There is no patch.

Step 2: Install and run TRANSVU, and select the tables you want to attach to the TAZ layer in TIGER/Line.

Step 3: Export the table (using the dbf or csv option) from TRANSVU.

2.3 Massaging the Data

Based on the software used, you may need to arrange the fields, and create “key” fields to join the data. For example, for export to Arcview, section 3.3 details a few steps.

2.4 Join the Tables Using Your GIS Software

Step 1: Open a new session of your GIS Software, and add the TAZ Layer to the view.

Step 2: Add the Exported dbf table.

Step 3: Open the attribute table associated with the TAZ layer, and the exported DBF table together. Highlight the TAZ fields in both, and join them together.

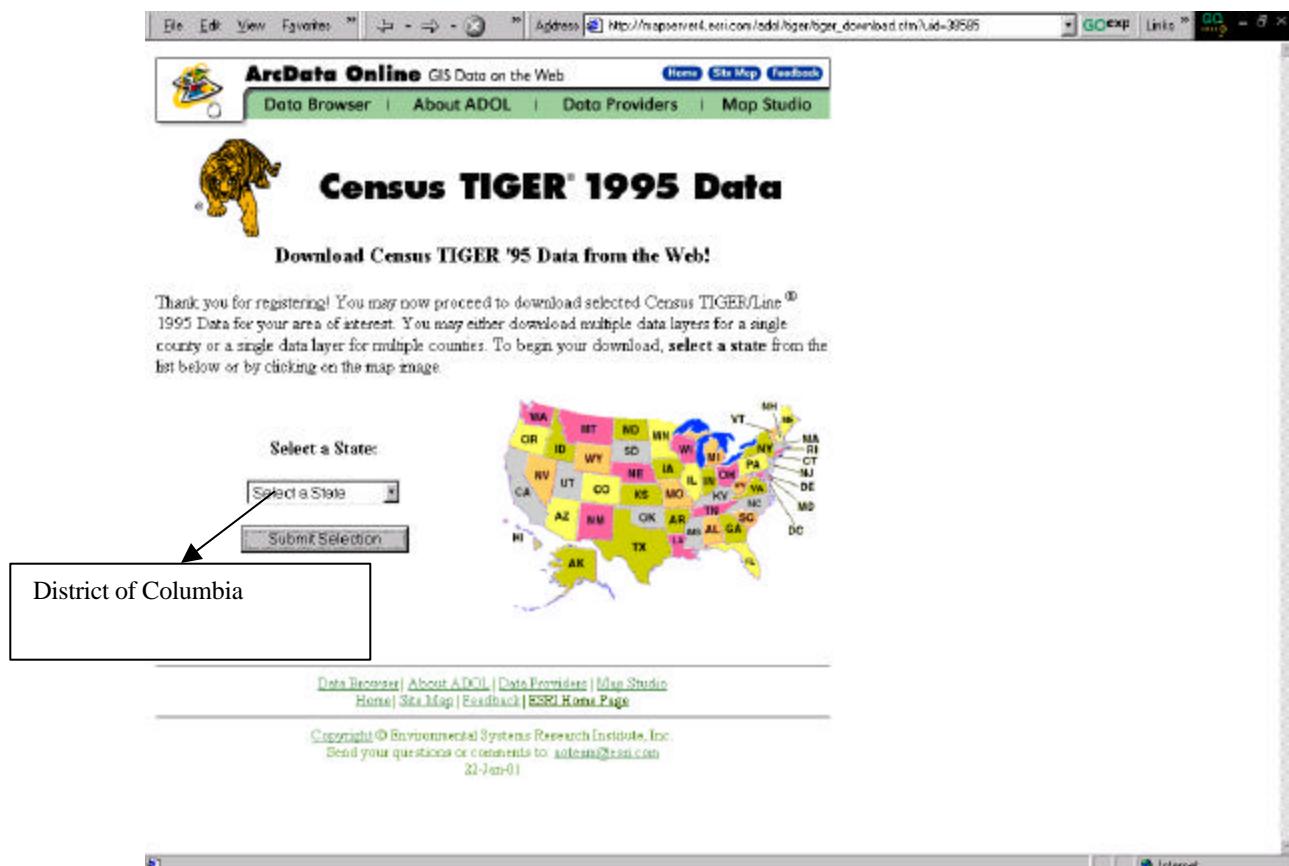

You can now do overlay analysis using the data fields in the 1990 CTPP.

3.0 Step-by-Step Instructions for the Washington, D.C. Area

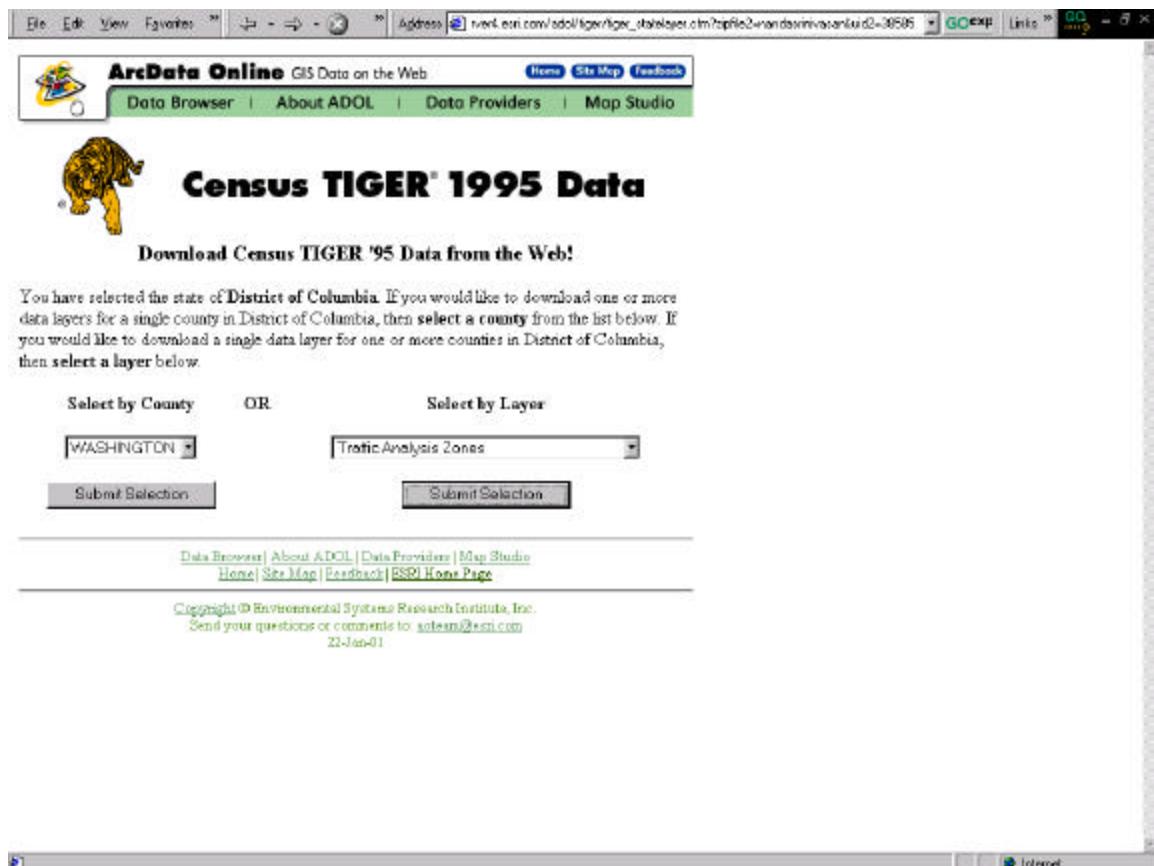

This section demonstrates the method outlined in Section 2. Washington D.C. is used as an example.

3.1. Prepare the Geography layer

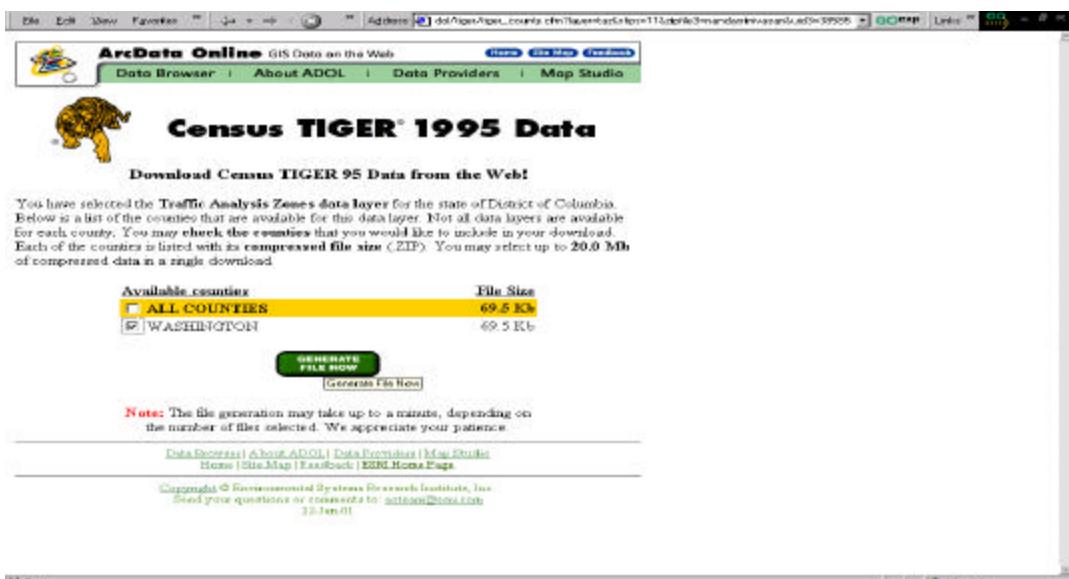

Step 1: Go to the ESRI website and in order to download the TAZ layer for Washington D.C. The URL is <http://www.esri.com/data/online/tiger/index.html>. You will need to register for free at the website for any downloads. In the screen that appears after completing registration, select Washington D.C.

Step 2: A new screen comes up with options on layers. Under select by layer, choose Traffic Analysis Zones (TAZs)

Step 3: On the next screen, choose the county you need (in this case Washington D.C. and generate the file. You can choose more than one county in the beginning, or even the entire state.

Step 4: The file comes in a zipped format. Download it and then use an Unzipping tool to extract the shape files. In this case, we saved the files to a new folder called d:\1990ctpp.

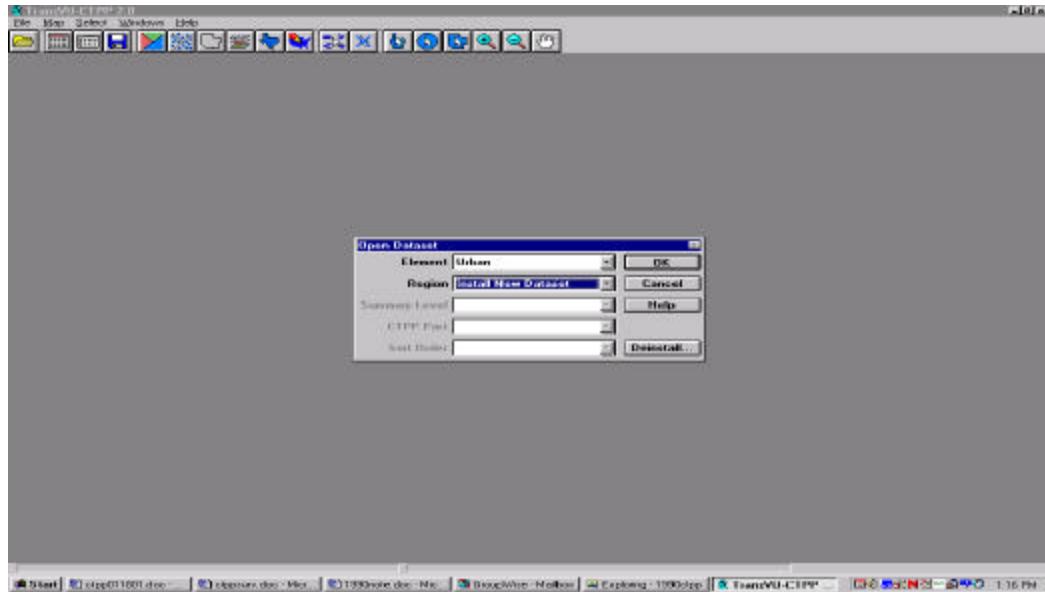

Step 5: Close internet explorer/Netscape/the web browser.

3.2 Download Transvu Software and Open a Session

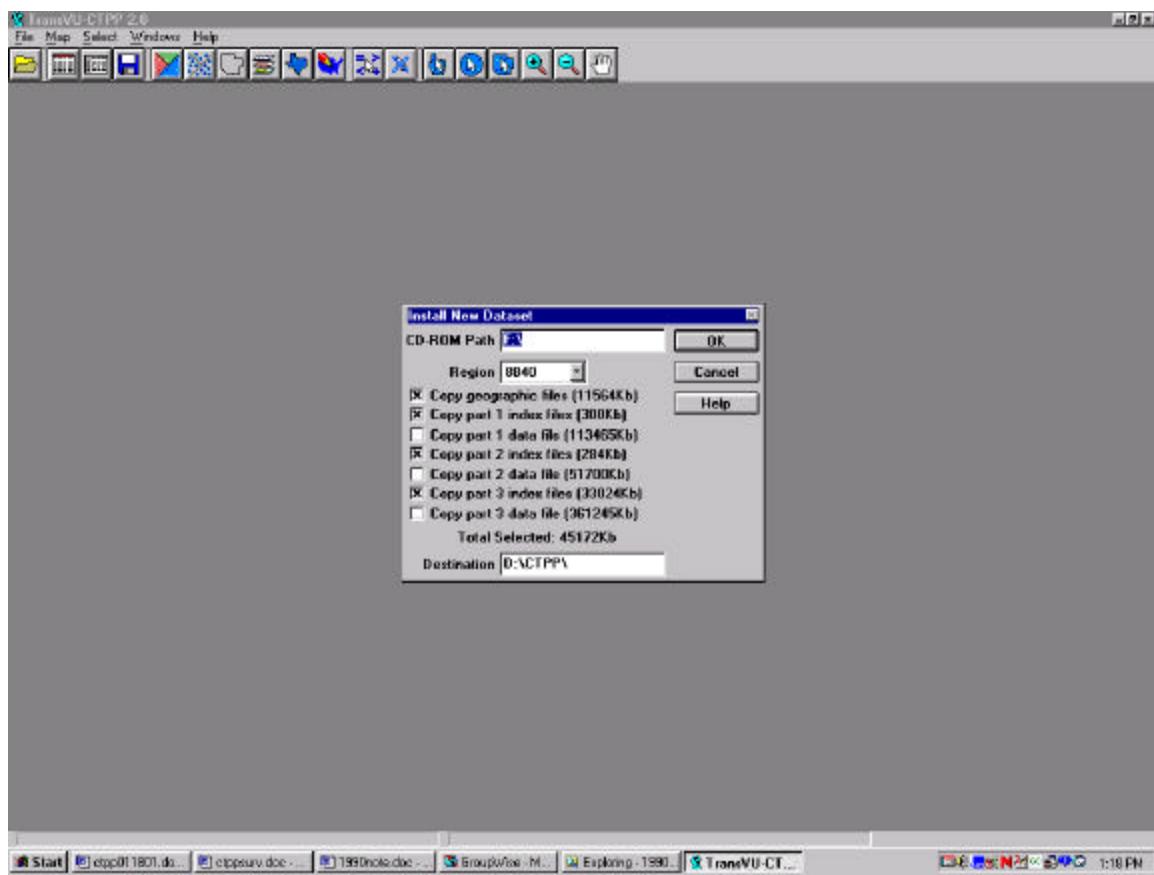

Step 1: TRANSVU can be downloaded from
<http://www.bts.gov/programs/btsprod/setupnt.exe>.

When this URL is accessed, a window pops up saying “You have chosen to download a file from this location. Run from current location or save to a disk.” You can either save the file to your hard drive or run the installation from the website. The installation typically takes 20 seconds. We used d:\transvu as the installation folder (You can choose any drive. For example, you may find more space on the c:\ drive).

Step 2: Run TransVu by double clicking on the icon the installation software creates for you. On the screen that appears, click on “Install new dataset” option. A new screen appears as shown below.

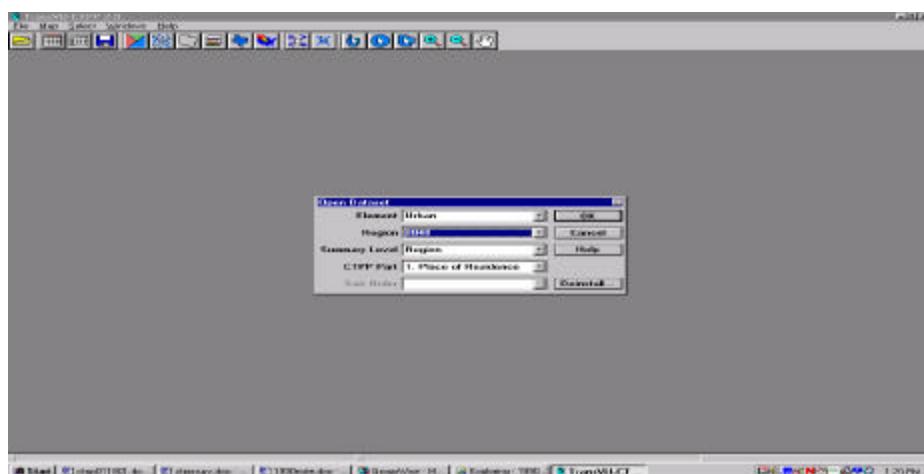

Step 3: Insert the CD containing data for your area. We inserted **the CD-ROM with the CTPP Urban Element for the District of Columbia, “BTS-05-16” CD-ROM**, and changed the path to f:\ drive (the CD-ROM drive on our machine). The following screen now appears.

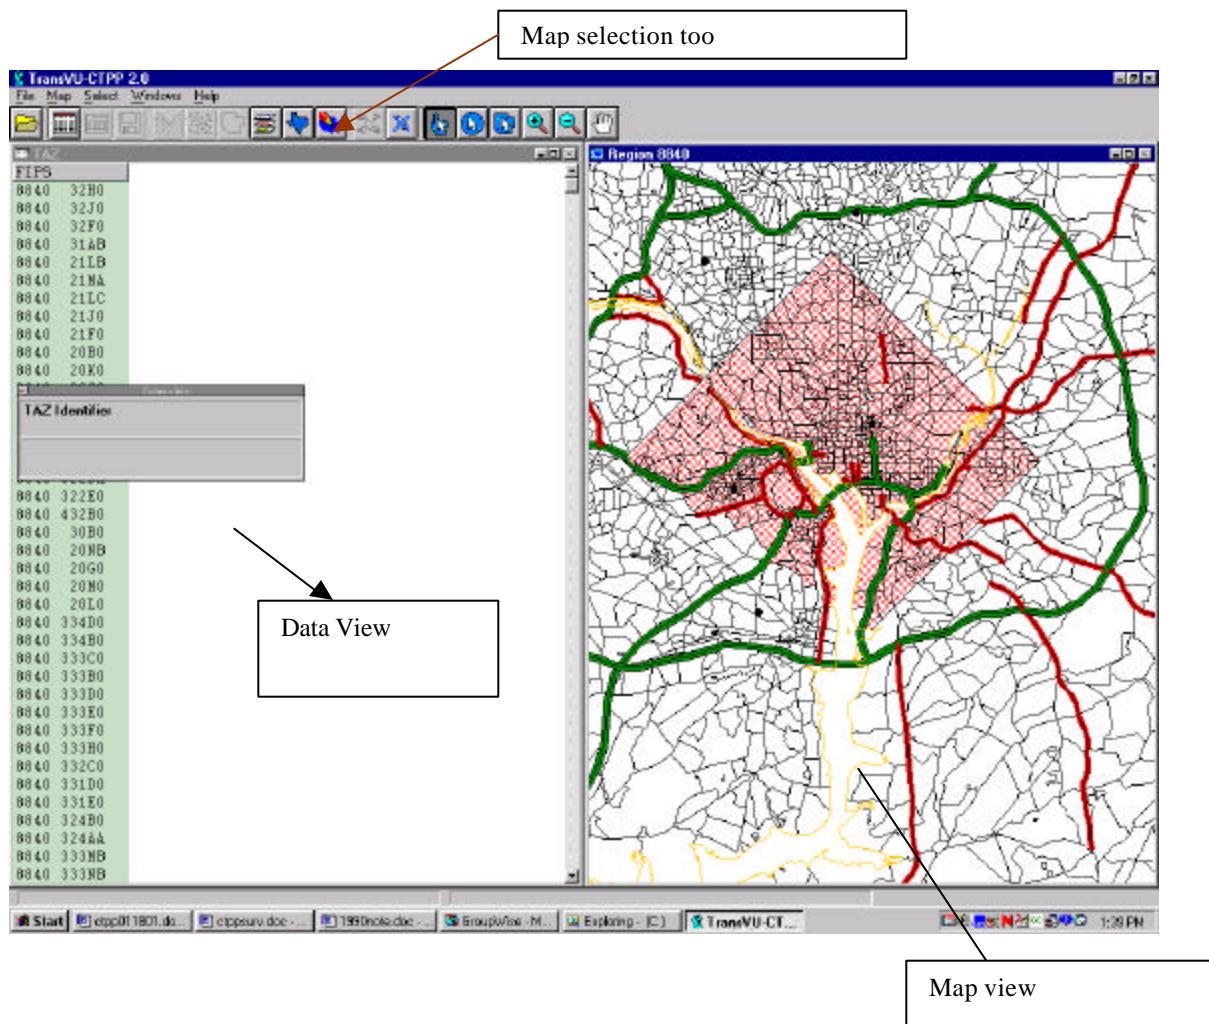

Step 4: Select all options and click ok.

Step 5: A new screen comes (as shown below). up with options on summary level and CTPP Part. We chose TAZ as summary level, and Place of residence, because we wanted to export place of residence data to the GIS. You can also choose place of work, or journey to work. For journey to work data, you need to consider that the matrices are large, and the flow data cannot be easily displayed graphically.

Step 6: A new screen comes up (as shown below), with a map-screen on one side, and the data screen on the other. Using the map selection tool, we selected all the TAZs we needed the data for. You do not have to do this, in case you want the entire data set to be exported, skip this step.

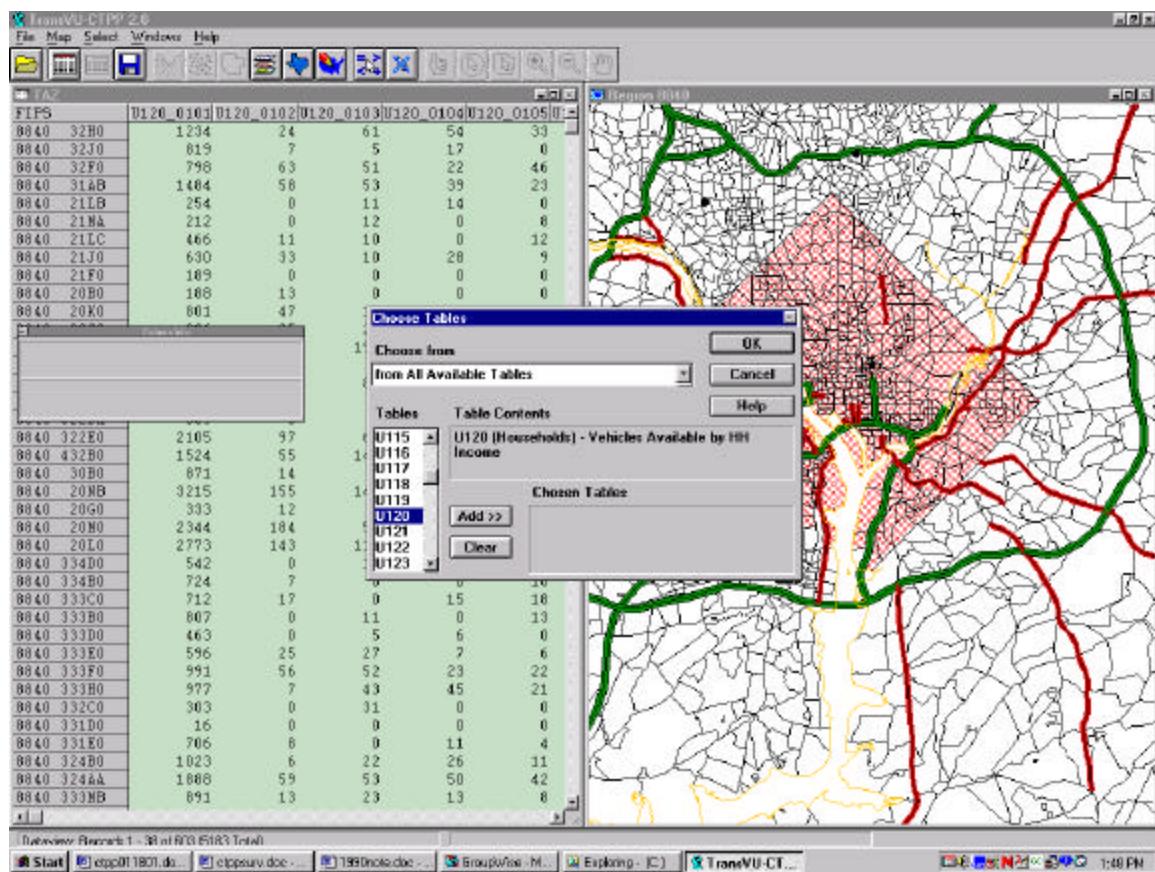

Step 6: Select the table(s) you want to export.

Using File → Choose Tables, we chose Table U120

This table contains counts of households stratified by household income and auto-ownership at the residential end.

Tip: By double clicking on a column, you can find out exactly what data the column contains.

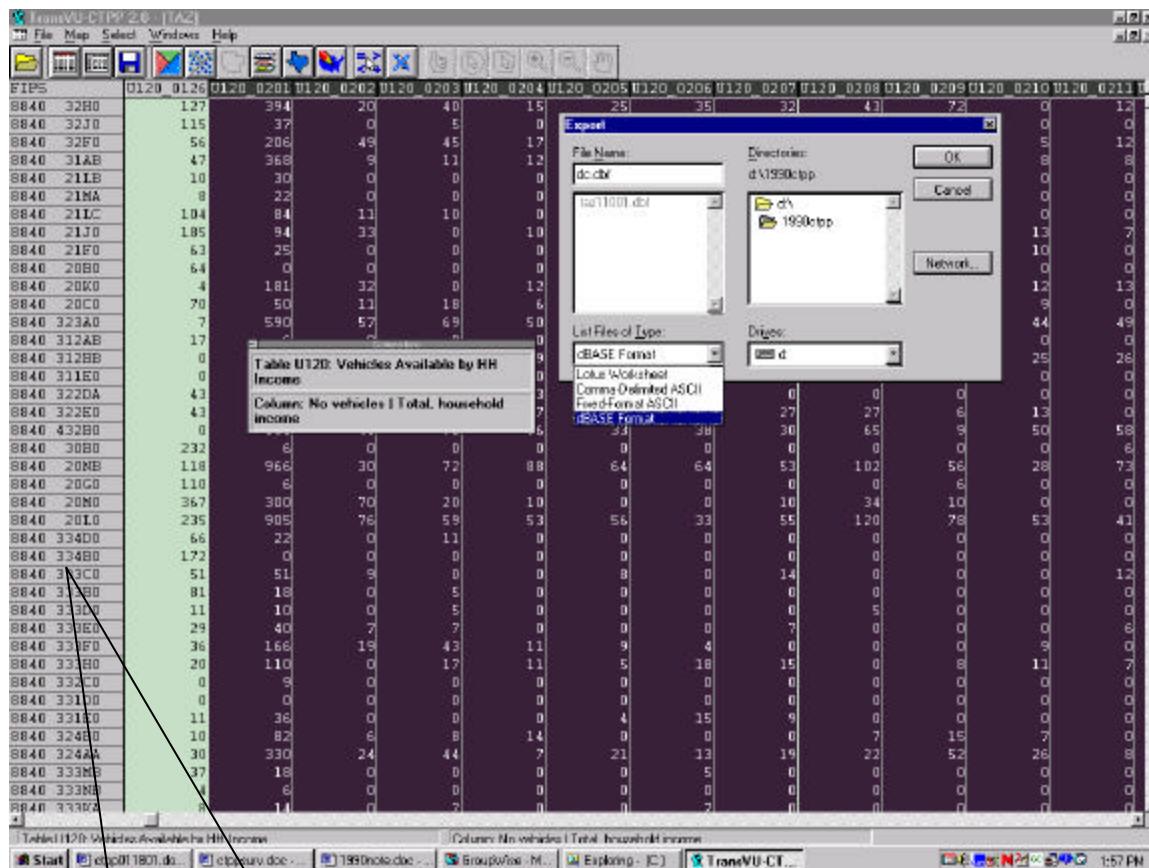

For example, the column highlighted in the screen shot below contains count of households with income range of \$17,500-19,999, and with no vehicles in the household.

8840 330BH0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
8840 330BI0	0	0	0	0	0	0</										

Step 7: Export to DBF Files.

We selected all columns and exported them as dbf format. Click on File and then Save As .dbf. We saved this file in d:\1990ctpp folder (the folder where we kept my TIGER/Line TAZ layer).

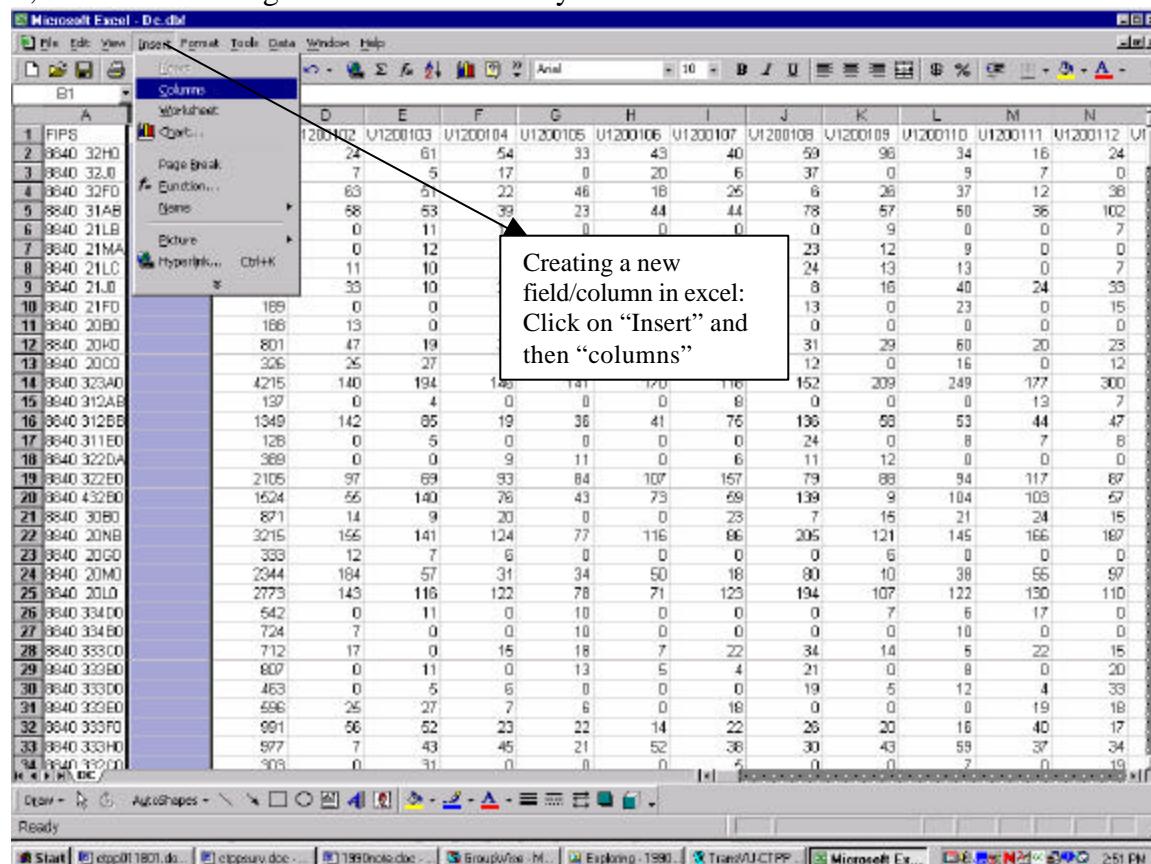

3.3 Massaging the Data

We chose ArcView as our GIS to import CTPP data. Since we intend to get this table to arcview, we need to create a column in both the CTPP table in dbf and the TIGER layer that will serve as the common field in a join. This field is called the key field in database jargon. The FIPS in TRANSVU actually contains a region code and the TAZ concatenated together. We need to separate the region code from the TAZ number.

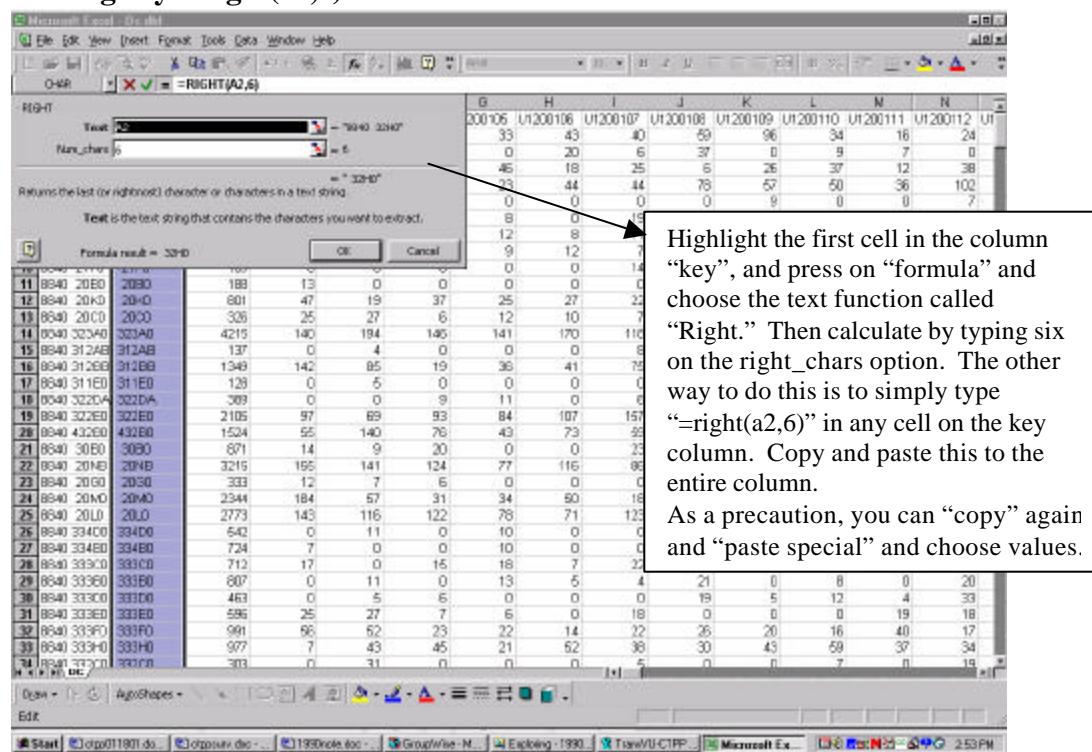

Step 1: To do this, we need to create a column for just the TAZ numbers. The CTPP table in dbf contains a regional code (shown above) plus the TAZ number. So, we opened the table dc.dbf in excel and created a new field called key. Next we entered the formula that will take just the right six numbers from the "fips" column and put them in the "key" column.

The following screen shots demonstrate how to create a new field/column in Microsoft

Excel, and calculate the right six fields into the “key” field/column.

Calculating key = right(a2,6)

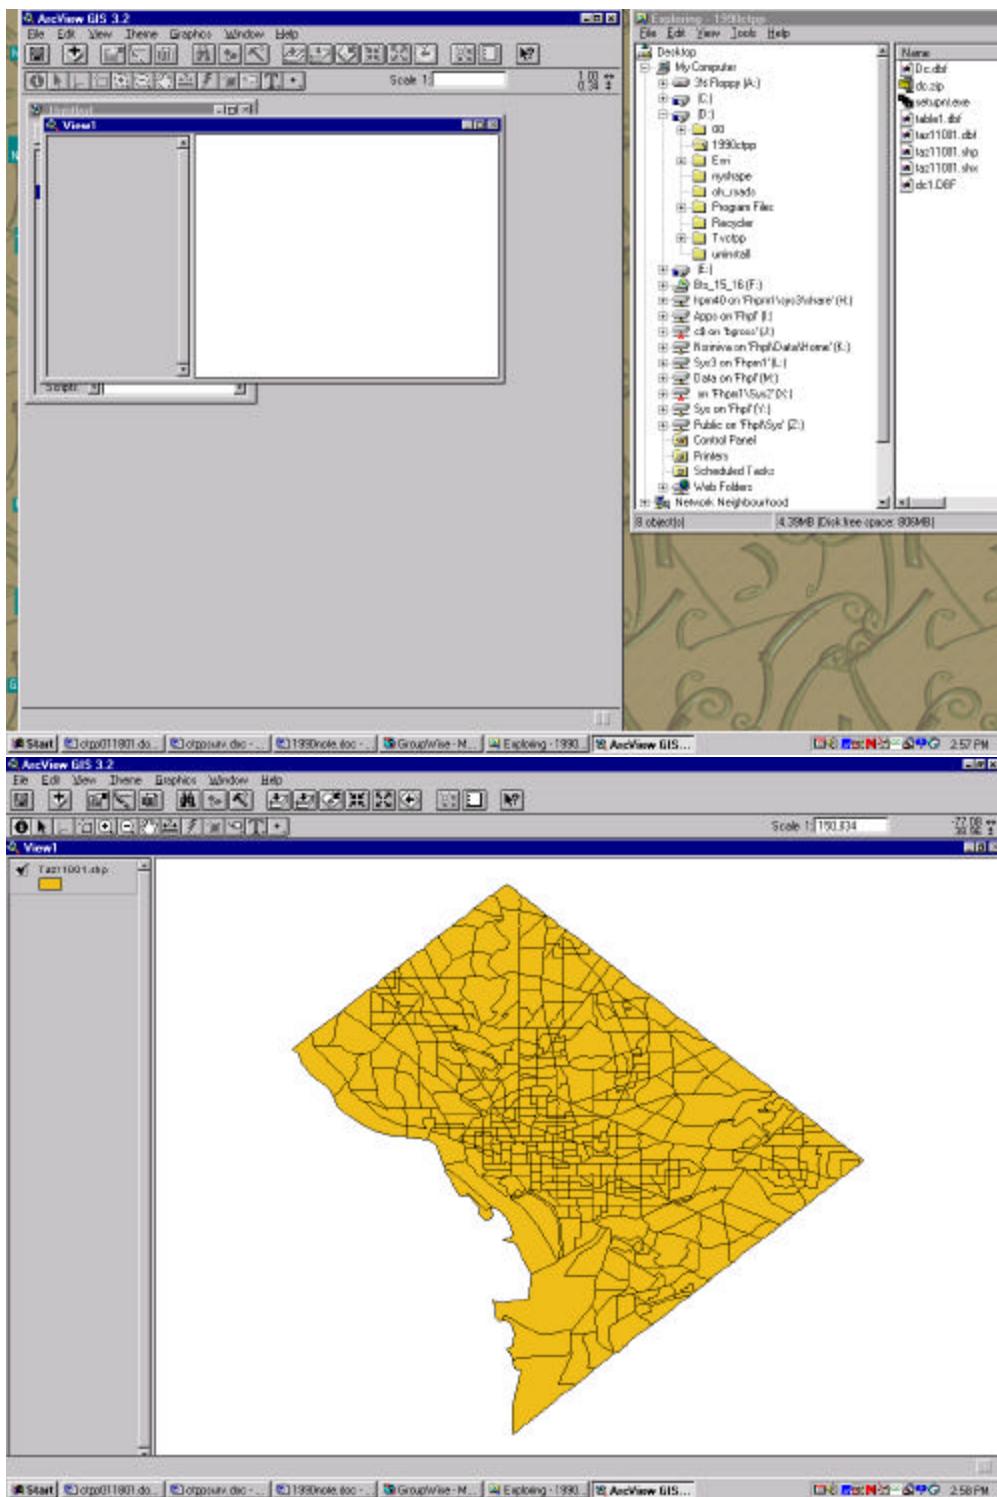

Highlight the first cell in the column "key", and press on "formula" and choose the text function called "Right." Then calculate by typing six on the right_chars option. The other way to do this is to simply type "=right(a2,6)" in any cell on the key column. Copy and paste this to the entire column.

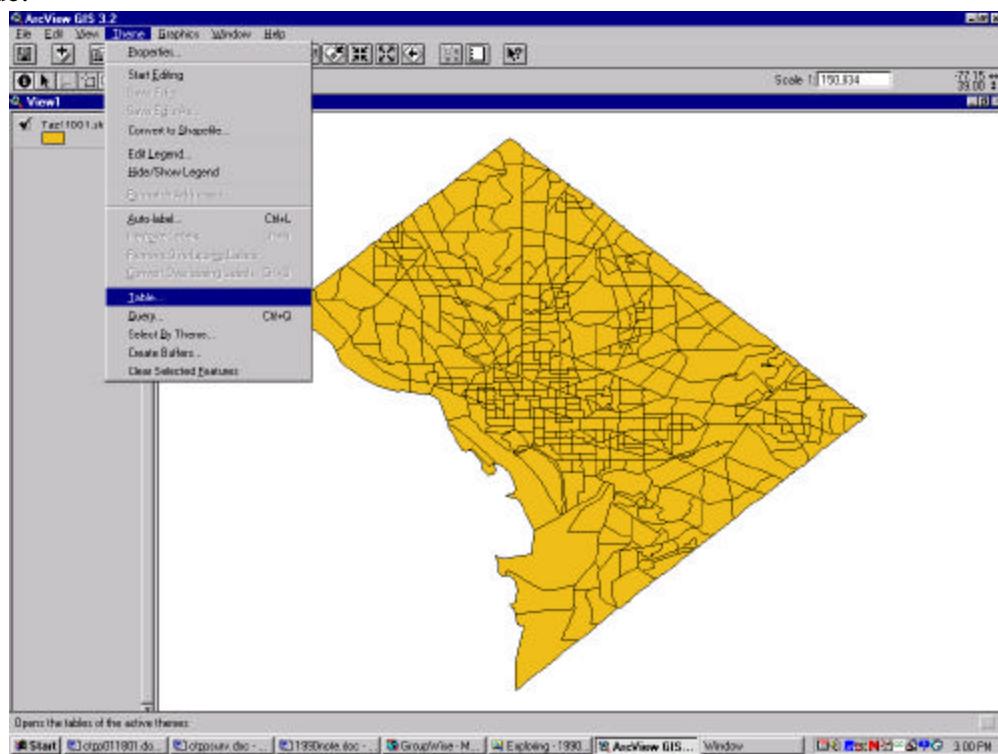

As a precaution, you can "copy" again and "paste special" and choose values.

We saved this as a new dbase file dc1.dbf. This is not really necessary, you could have over written the old file.

Step 2: Start a new Arcview session, add a view, and add the shape file for Washington, D.C. from the folder (d:\1990ctpp\).

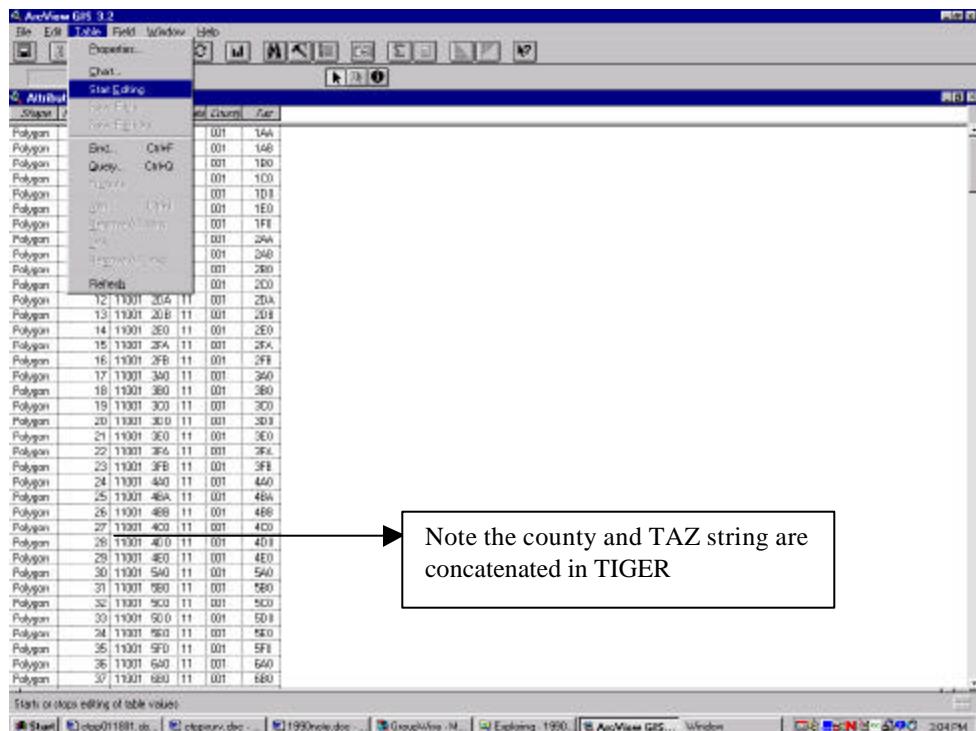

Step 3: Open the attribute table for this shape file by clicking on “theme” then “table”, and do the same massaging as the CTPP Data file. This is because the TAZ field in the attribute table for the TIGER Shape contains the “county” code concatenated to the TAZ code.

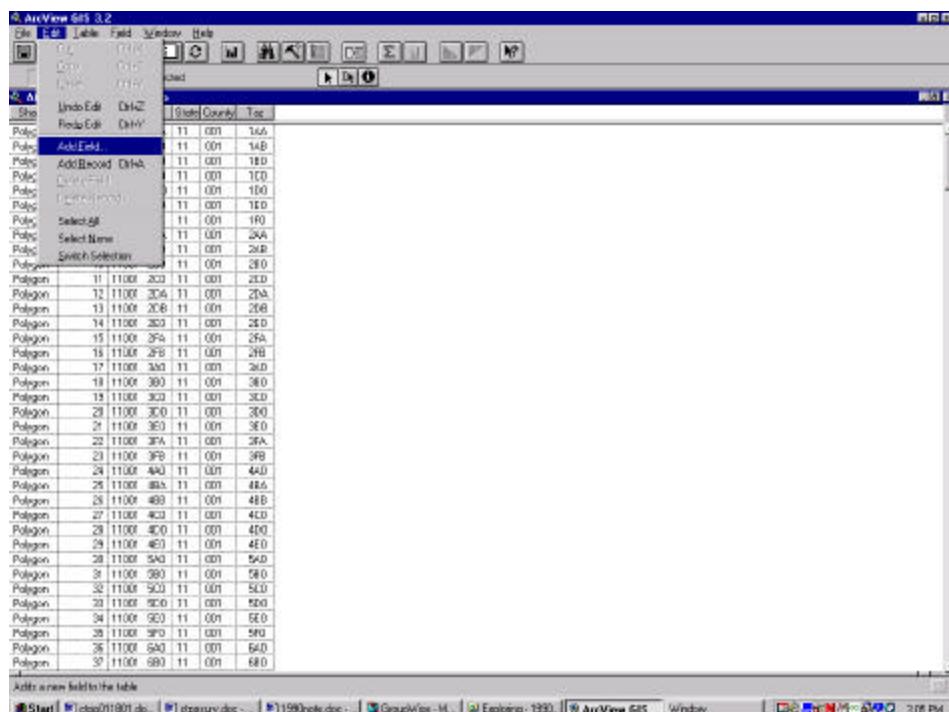

Shape_Record_id	Key	State	County	TAZ

The screen shots above demonstrate how to view the table for the shape file added in the view.

Step 4: Put the table in “edit” mode by clicking on “table” and “start editing” as shown below.

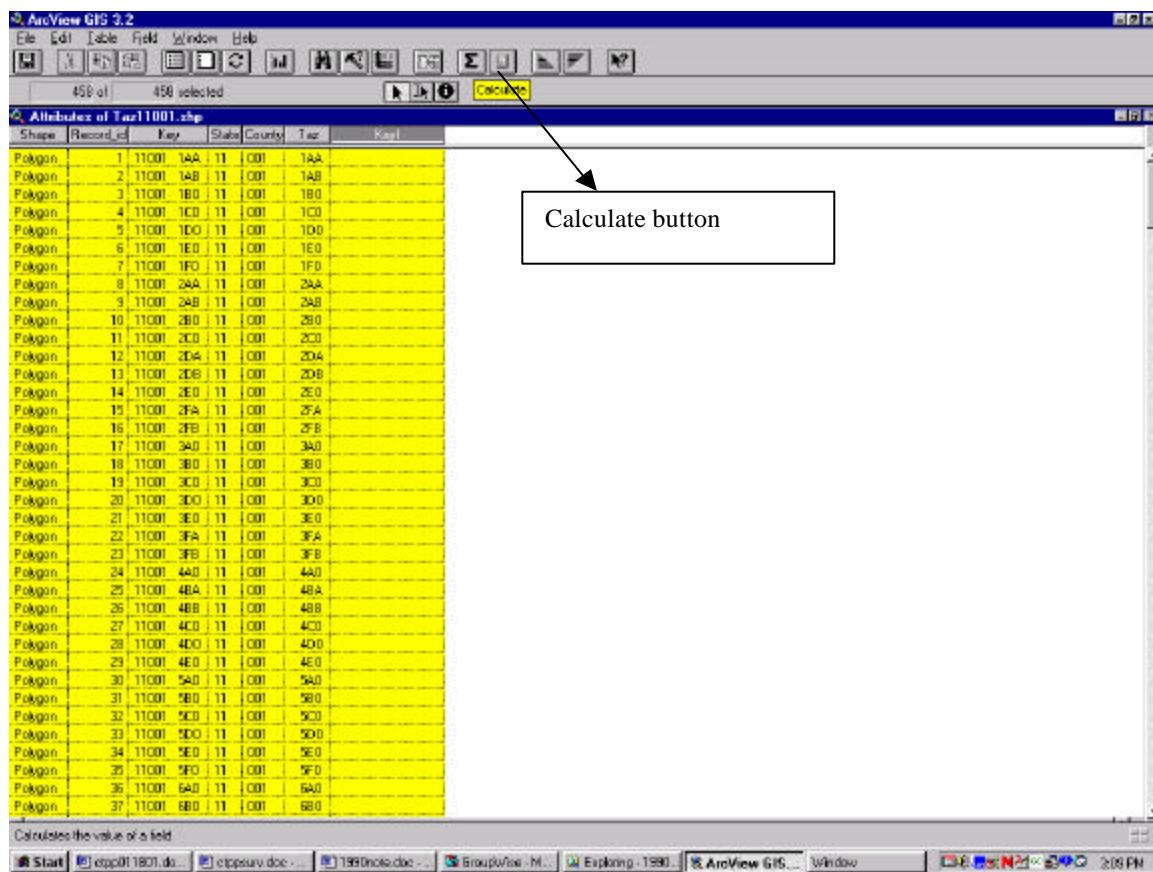

Step 5: Add a new field/column by clicking on “edit”, add then “add field” as shown below

Step 6: Make this field a “string” (ArcView’s name for a character field), and calculate it as the right 6 characters of the County + TAZ field. We called this new field “Keyf.”

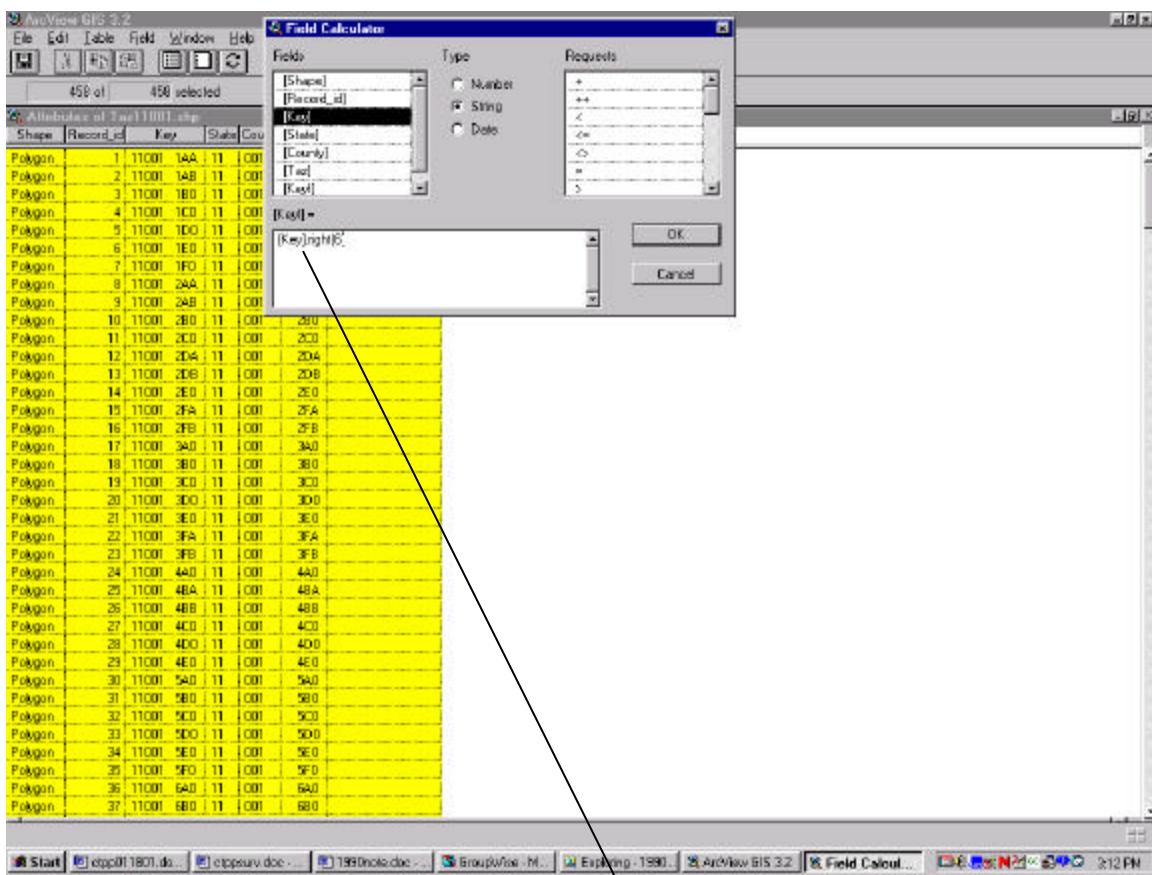

Demonstration:

Select all records and press the calculate button. To select all records Click on “edit” and then “select all.” All the rows now get highlighted in yellow. Now click on the header “keyf” so it gets highlighted in dark grey. Press the “calculate” button as shown in the following screen-shot.

In Arcview the syntax is Keyf = [key].right(6)

This will calculate all the rows in the column (field in ArcView) as the 6 right most characters in the “Key” field (the County +TAZ Field). The heading on top of the column should be keyf. We highlighted that field, and then pressed the calculate button. The following screenshot should appear.

Calculate button Screen

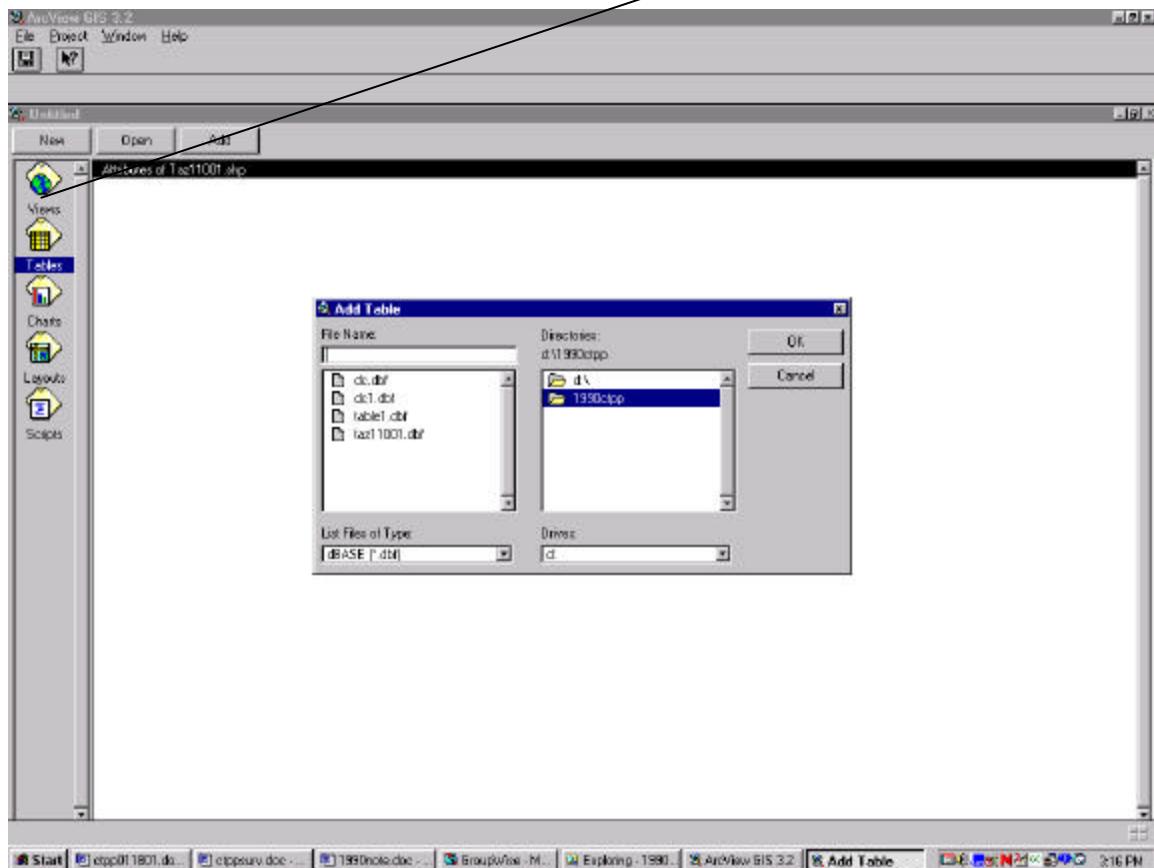

In the box that appears, We typed in [KEY].right{6}

Step 7: We then saved the edits in the table and deselected all the records. The new table looks like this:

	Shape	Record_id	Key	State	Count
Polygon	1	11001	1AA	11	1001
Polygon	2	11001	1AB	11	1001
Polygon	3	11001	1B0	11	1001

Polygon	37	11001	6B0	11	1001

3.4: Add the massaged CTPP Table into ArcView and join it with the geography file.

Step 1: Add the ctpp table (dc1.dbf) using **ADD TABLE** from the Arcview project directory:

Step 2: Open both the tables by double clicking on them, and arrange the sizes of their windows so that they can be viewed simultaneously. The next screen shot shows how the computer screen should look.

Step 3: Viewing both the tables together, click on the “key” field in dc1.dbf, and the “keyf” field in “Attributes of 11001.shp” (the order is very important).

Step 4: Click on the “join” button to (“finally”) attach the datafile to the shapefile. Congratulations. You have now transferred your CTPP Data file into a GIS. You can now either save the shapefile into another new shape file, or just save the Arcview project. The following screen shot suggests how the new “Attributes of TAZ11001,SHP” table should look. You can now go to the “view” and make some colorful plots!
